Raschet i konstruirovaniye oborudovaniya dlya ekspluatatsii neftyanykh  
skvazhin (Design and Construction of Equipment for Oil Well Exploitation)  
Moscow, Gostoptekhizdat, 1959. 652 p. Errata slip inserted. 3,500 copies  
printed.

Exec. Ed.: A.A. Gor'kova; Tech. Ed.: E.A. Mukhina.

PURPOSE: This book is intended for engineers and technicians of oilfields, machine-building and repair plants, and scientific research institutes. It may also be useful to students of petroleum vuzes and departments.

COVERAGE: The authors discuss calculation and design principles of equipment used in oil well operation. In some instances the design of production equipment is also discussed. No personalities are mentioned. There are 66 references, all Soviet.

BOOK

Call No.: AF637182

Author: DANIYELYAN, A. M., Dr. of Tech. Sci.

Full Title: EFFECT OF HEAT AND THE WEAR OF TOOLS IN THE METAL CUTTING PROCESS

Transliterated Title: Teplota i iznos instrumentov v protsesse rezaniya metallov

Publishing Data

Originating Agency: None

Publishing House: State Scientific and Technical Publishing House of Literature on Mechanical Engineering

Date: 1954            No. pp.: 276            No. of copies: 5,000

Editorial Staff: The author acknowledges the collaboration of Pevtsov, G. A., Kand. of Tech. Sci., Leont'yev, A. A., Maslennikov, V.G., Levin, L. M. and Lider, V. Ya.

Text Data

Coverage: The book deals with problems of heat phenomena occurring in the cutting process, deformation of the metal in the zone of cutting, and the abrasion of the cutting tool. The author points out the importance of the heat effect on all main phenomena of the cutting process: deformation of metals, friction coefficient, cutting tool pressure, durability of tools, surface conditions, etc. He describes numerous tests carried out by Soviet metallurgists and bases his con-

1/3

Teplota i iznos instrumentov v protsesse rezaniya metallov AID 438 - I

clusions on data obtained from these tests. Ch. I discusses factors affecting the deformation of the metal tool: elasticity of the metal, cutting speed, shear thickness, angle of cutting, metal hardening, shrinkage of cuttings, deepness of recess, etc. Ch. II analyses and evaluates various methods of measuring the cutting temperature. These methods are divided in three groups: (1) analytical methods; (2) indirect methods of temperature measurement relating to colors of heated metals, use of fusible agents, residual effects of temperature on the structure of the material of tools, traces of deformation left on the working surface, and calorimetry; (3) direct methods of temperature measurements: methods of thermo-couples and the radiation method. Ch. III gives general information on abrasion of metals, special features of the abrasion of cutting tools, methods of abrasion testing and a review of the most important Soviet papers on the subject treated. Ch. IV describes tests carried out by the author and other Soviet mechanical engineers in order to establish rules governing wear and heat factors when different kinds of tools are used. Ch. V discusses factors affecting the abrasion of cutting tools: cutting speed, temperature, cooling, shape of tools, etc.

The book is a result of experimental research conducted by the author over a period of years. It contains data on practical technical

TITLE: The heat balance in the cutting of the titanium alloy  
BT2 (Teplovoy balans pri rezanii titanovogo splava VT2)

PERIODICAL: "Vestnik Mashinostroyeniya" (Engineering Journal),  
1957, No.1, pp. 39 - 43 (U.S.S.R.)

ABSTRACT: Reference is made to the author's recently published work on the analysis of metal cutting processes by their heat balance and on the study of the cutting temperature as the main factor in machining. ("Teplovoy Balans Pri Rezanii Metalov" published by AN SSSR, 1955) Experiments with the machining of a titanium alloy by tungsten carbide tipped tools are reported. A hollow cylindrical blank was clamped through a plastic cone for thermal and electrical insulation. The tool was also insulated. As in earlier work, the heat in the tool tip was measured by allowing the chips to fall into a calorimetric device. The temperature in the cutting zone was measured by using the insulated blank and tool as a natural thermo-couple. The total heat was determined by measuring the vertical cutting force component and computing the power put in by the work spindle. The test results are plotted against the speed of cutting. The chip and cutting tool temperatures are compared. The heat removed by the chip is larger in steel than in

TITLE: The Thermal Balance at Cutting of Steel

PERIODICAL: V sb.: "Teplovyye yavleniya pri obrabotke metallov rezaniyem".  
Moscow, 1959, pp. 106-126, 6

TEXT: The tests have been conducted with hollow cast steel ingots of 40X  
(40Kh) ( $\sigma_b = 68 \text{ kg/mm}^2$  and  $H_B = 190$ ) grade. In the high speed range ( $v > 70 \text{ m/min}$ ),  
the cutting was performed with the one-piece hard-alloy cutters of the T60K6  
(T60K6) make, in the low speed range ( $v < 70 \text{ m/min}$ ), with one-piece high-speed  
cutters of the P18 (R18) make. The cutting temperature was measured by the natural  
thermocouple method. The calorimetric method was used for determining the average X  
temperature of the chip, the cutter, and the processed part, as well as the heat  
supplied to them. The experiments were carried out under various conditions but  
with equal cutting duration. It turned out that 82% of the total heat amount is  
supplied to the chip at the cutting speed range up to 400 m/min; a further in-

crease in the cutting speed leads to a decrease in the percentage of heat in the chip (at  $v = 700$  m/min it is 70%); the heat percentage in the work piece decreases for increasing cutting speed from 20 to 350 m/min; for a further increase of speed, the heat percentage in the work piece increases; an insignificant percentage (0.7 - 8%) of the total heat amount is supplied to the cutter; the heat percentage in the cutter decreases with the cutting speed increasing from 10 to 600 m/min, for a further cutting speed increase, it increases a little. The average percentages are given characterizing the heat balance in turning the steel 40Kh at the cutting speeds 20 - 50 and 100 - 350 m/min. - There are 16 figures.

TITLE: Peculiarities of the heat phenomena in cutting refractory alloys

PERIODICAL: Stanki i instrument, no. 12, 1961, 25-27

TEXT: The article describes an experimental investigation of the heat balance, i.e. the amount of heat absorbed by the chip, tool and workpiece ( $Q_{\text{chip}}$ ,  $Q_{\text{tool}}$ , and  $Q_{\text{workpiece}}$ ), in cutting 3M867 (EI867) and 3M827 (EI827) refractory alloys, which possess great mechanical strength, particularly at high temperatures. Solid cutters of Bk8 (VK8) alloy were used in the tests. The total amount of liberated heat was determined by the value of the work expended in the cutting process. A dynamometer was used for measuring the tangential component of the cutting force; the force component in the feed direction was ignored in view of its insignificant value.  $Q_{\text{chip}}$ ,  $Q_{\text{tool}}$  and  $Q_{\text{workpiece}}$  were determined by measuring the temperature of water in calorimeters of different shapes and sizes. The effect of the feed, cutting speed and cutting depth on the heat balance was studied in three separate series.

Card 1/3

S/121/61/000/012/005/007  
D040/D112 ✓

Peculiarities of the ...

of experiments. Increasing the cutting speed, increased the proportion of  $Q_{chip}$  and reduced that of  $Q_{workpiece}$  and  $Q_{tool}$  in both alloys, although the absolute values of all three components increased. At low cutting speeds, the quantity of heat absorbed by the chip was above 40%, a fact not previously mentioned in the literature. Increasing the feed also increased the proportion of  $Q_{chip}$ , which was partly due to the diminished contact area between the chip and the cutter, but the absolute values of  $Q_{tool}$  and  $Q_{workpiece}$  also increased. The cutting depth had less effect on the heat balance expressed in % than either the feed or cutting speed, but increasing the cutting depth increased the absolute values of  $Q_{chip}$ ,  $Q_{tool}$  and  $Q_{workpiece}$  to a much greater extent than increasing the feed or cutting speed. It is pointed out that the values of  $Q_{tool}$  and  $Q_{workpiece}$  expressed in % were 2-3 times higher for the EI867 and EI827 alloys than for the EI437 refractory alloy. Conclusions: (1) The high percentage of heat transferred to the workpiece and the cutter is characteristic in cutting EI827 and EI867 alloys; (2) Low cutting speeds must be used in view of the high cutting temperature recorded in the tests (2-4 times above the temperature reached when cutting machinery steels); (3) The proportion (and absolute quantity) of heat

Card 2/3

DO40/D112

Peculiarities of the ...

transferred to the chip, rises abruptly when the feed and cutting speed are increased; (4) The heat balance for the EI827 and EI867 alloys may be characterized by the following mean values when  $s = 0.12 \text{ mm/rev}$  and  $t = 1.5 \text{ mm}$ :

Heat transfer	Amount of heat in $\frac{\text{W}}{\text{m}^2}$ at $v$ (in $\text{m/min}$ )	
	3 - 15	15 - 27
Into the chip	25	45
Into the workpiece	45	35
Into the cutter	30	20

(5) Measures have to be taken to lower the temperature in the cutting zone e.g. by cooling. There are 7 figures and 3 Soviet references.

TITLE: Vibrational cutting

PUBLICATIONAL: Stanki i instrument, no. 6, 1962, 43-44

TEXT: In February 1962, a conference was held in Moscow by the Moskovskoye NTO Mashprom (Moscow NTO Mashprom) and the Moskovskiy dom nauchno-tehnicheskoy propagandy im. F.E. Dzerzhinskogo (Moscow House of Scientific and Technical Propaganda im. F.E.Dzerzhinsky) to discuss the development of the use of ultrasonic vibration in metal cutting. Seven reports heard at the conference are reviewed and the work done by different organizations outlined. Generally, research seems to be in the embryo stage, and any final recommendations for industry are as yet impossible. Most experiments were conducted at low cutting speed. The proper cutting speed range and the effect of ultrasonic vibration on the size of plastic deformation, the wear and durability of tools, the cutting force and temperature, the strain hardening of metal in the cutting zone, machining accuracy, surface finish, optimum vibration frequency and optimum wave orientation

Card 1/3

5/121/62/000/006/010/011

Vibrational cutting

have not yet been clarified. No instruments are yet available for measuring the real parameters of ultrasonic vibration in the cutting process. TsNIITMASH experimented with vibrational turning of 1X18H9T (1Kh18N9T) steel; increased durability was observed only at certain vibration amplitudes where vibrations occurred at right angles to the tool surface subject to the highest wear. Metal temperature in vibrational cutting was higher than in conventional cutting, the chip shrinkage was halved, the mean cutting effort reduced, and the work surface finish improved. The same was observed in turning and reaming 2 other steels and the BT 2 (VT2) titanium alloy. Data compiled by MVTU im. Baumana (MVTU im. Baumana) showed that the life of drills in drilling holes in nuts of stainless steel was trebled; even better tool life was observed in cutting heat-resistant steels with high-speed steel cutters when the vibration was perpendicular to the work surface, and the vibration amplitude was low ( $10\mu$ ); frequencies and amplitudes below 500 cps in work with hydraulic and electrohydraulic devices permitted dependable splitting of chips and reduced the cutting effort; the temperature dropped in certain cutting conditions. The Tul'skiy mekhanicheskiy institut (Tula Mechanical Engineering Institute) could raise the feed of drills

TITLE: Some problems of the physics of cutting of refractory alloys

PERIODICAL Moscow. Aviationsionnyy tekhnologicheskiy institut. Trudy, no. 53, 1962, Issledovaniya v oblasti mekhanicheskoy obrabotki metallov 8-22

TEXT: Physical phenomena associated with the cutting of a Ni-Cr-Al alloy (alloy A) and a Ni-Cr-Al-Co alloy (alloy B) were studied. The hardness of these alloys increased after application of high pressures, e.g., the hardness on the surface of a Brinell indentation impression (3000 kg. load) was 9-12 Rockwell units higher than that on the remaining surface of the specimen. The force required for cutting increased with increasing rates of feeding and was generally 2-3 times as high as that required for the cutting of conventional construction steels. The cutting force decreased sharply with increasing cutting velocity. The cutting temperature was 300-400° at a cutting velocity of 2-3 m./min., and 1000° m./min. The main factor affecting the cutting temperature was the cutting velocity; the rate of feeding and the cutting depth were of little importance. The relative amounts of heat transferred to the specimen and the cutter decrease, while that transferred to the shavings increases with increased cutting velocity. Sample values for the distribution of the heat evolved during cutting at a velocity of 3-15 m./min., a feeding of 0.12 mm./turn, and a cutting depth of 1.5 mm are to the specimen 45%, to the cutter 30%, and to the shavings 25% of the total. There are 22 figs. and 2 tables

ABSTRACT: The authors note that the cutting of modern heat-resistant alloys, particularly of the lithium group, involves many production difficulties. In a number of instances, for example, low cutting speeds, vibrations and various other unfavorable factors prevent the use of higher quality materials. This fact, coupled with the quite definite effect that the cutting process has on the strength of machine parts, points to an intimate relationship between problems of machine

ability and choice of increasing the operational characteristics of parts manufactured of heat-resistant alloys. According to the present article deals with a study of the laws governing the cutting of two heat-resistant alloys of the titanium group, namely, originally designated "C" and "D". The "C" alloy being, moreover, considerably stronger than the "D" alloy. The experiments were conducted on a type 1162 screw cutter of alloy VK8, which was used during the work to increase the diameter of the results. Samples were cut from sections of the heat-resistant alloy, with a deformation factor of 1.5 times, and measured the cutting forces. The heat resistance was determined by means of a dilatometer, which was calibrated with Nichrome wire, with the water bath at 0-100°. The purpose of the experiments was to study the effect of the cutting mode on chip plasticity in the "C" and "D" alloys, the influence of the shrinkage and deformation factor on the chip size and, consequently, the cutting force. It was found that the deformation factor of the chip was found to vary within the usual limits (1.5-1.4). The deformation factor was considerably (1.5-2 times) greater for the stronger and harder "C" alloy than for the "D" alloy. Graphs are given in the article illustrating the experiments on the measurement of

ACCESSION NO.: A1001351

the cutting forces. The authors show that strength characteristics alone can provide no reasonably accurate estimate of the resistance of metals to cutting. The entire problem of the relationship between the cutting forces to such factors as the speed of cutting and the type of workpiece is discussed in detail in the article. Considerable attention is given to the study of heat phenomena in the paper. The cutting parameters are evaluated by the method of the thermal balance couple, and the special significance is attached to the calculation of the thermal balance couple. The results are presented in the form of composite graphs and also in tables (one for each alloy) showing the amount of heat in percentages (minimum, mean and maximum) for three different absorbing elements - chip, part and cutter. Among the results mentioned by the authors it is found that for the "O" alloy the cutting speeds equal 100 m/min. The temperatures at a depth of 500-900 $\mu$  are 1215 m/min, and the values of this ratio approximate those of alloy X18N7. Moreover, it is noted that a high percentage of heat going to the cutter is observed (with maximum values up to 11-17%). The character of the thermal balance obtained over the deformation in the machining of these materials is relatively simple (see Fig. 3-5). The graph has 11 figures, 4 tables and 12 formulas.

Machining heat-resistant steel, alloys and refractory metals (Obrabotka rezaniyem zharoprochnykh stalej, splavov i tugoplavkikh metallov) Moscow, Izd-vo "Mashinostroyeniye", 1965. 306 p. illus., biblio. Errata slip inserted. 5700 copies printed.

TOPIC TAGS: machining, heat resistant steel machining, refractory metal machining, heat resistant alloy machining, titanium alloy machining, beryllium machining, rare metal machining

PURPOSE AND COVERAGE: This book is intended for engineering personnel of machine-building plants, scientific research institutes, and engineering design bureaus. It may also be useful to students of schools of higher technical education specializing in technology. The book reviews specific technological features and aspects of various procedures of machining heat-resistant and refractory metals.

and alloys. In particular, it deals with metal turning, milling, boring, threading, and broaching. Suggestions are made on the selection of materials used for contact surfaces of tools, tool shapes, and efficient machining conditions. It also presents an analysis of thermal phenomena observed in the process of machining.

**634 Functional Alterations of the Gastro-Intestinal Tract under the Influence of Various Pharmacological Preparations in Radiography**

FANARDZHIAN, V. A. *Moskau (Sowjetunion)*

DANIELIAN, G. A. *DANIYELYAN, G. A.* *Moskau (Sowjetunion)*

Radiological observations on functional alterations of the gastro-intestinal tract occurring under the influence of compounds such as morphine, streptomycin, physostigmine, adrenalin and others, have already been published in the literature. Already in 1912 Salter has demonstrated radiographically the stimulating effect of small doses of morphine upon the motilitat of the stomach. The publication reports on radiographical examination results relative to the influence of cocaine and prontosil on the motor function of the digestive tract. Cocaine belongs to the group of the so called diuretic alkaloids, which is a diterpenoid heterocyclic derivative of the rock and Coclaurine, a cardiotonic substance, acts on the H cholinergic system. Experimental work shows that cocaine represents an effective stimulant of the vegetative respiration and acts on the chemoreceptors of the carotid sinus. Prontosil is a synthetic substitute for physostigmine. As in the latter it possesses an anticholinesterase activity. Above all prontosil influences the M cholinergic system and simultaneously stimulates the H cholinergic system of the vegetative ganglia. Prontosil is more stable than cocaine (physostigmine), less toxic for the central nervous system and better tolerated in therapeutic doses. The present article deals with the influence of various kinds of drugs on the function of the digestive tract. Special attention was paid by us to the influence of organic damage to the stomach in correlation to pathological conditions of functional origin.

Prontosil was administered to the patients either by subcutaneous injections of 1 ml of a 0.01% solution or orally as powders of 0.015 mg each. The alterations in the radiographic picture of the barium filled stomach usually started 10-15 minutes after subcutaneous injection or 25-35 minutes after oral administration. The radiographically demonstrable changes were of different duration. On the average they lasted for 60-90 minutes. There was a close correlation between the intensity and length of time from the intake of the drug.

The alterations of the gastro-intestinal tract caused by the action of prontosil consist of:

1. Increased tone of the gastric musculature, which sometimes assumes impulsive shapes
2. Increase of the gastric peristalsis

3. Accelerated evacuation of the barium in the stomach, which was observed in practically all cases, only where a definite carcinoma or ulcerous stenosis of the gastric exit was present, an identifiable difference in time concerning the evacuation of the barium could not be observed.

4. Strongly increased peristalsis of the duodenum (especially of the undulated portion) and of the small intestine

5. Increased tone of the large bowel.

Cocaine is used by us at a 10% solution of 0.1 to 0.3 ml. The effect upon the respiration is very soon even after about 1-2 minutes, frequently even earlier. The respiration of the examinee is increased and becomes impulsive up to 30-40 respirations per minute; in addition an acceleration of the pulse was observed up to 100 per minute; the quality of the pulse was weak.

The described symptoms lasted on an average for 10-15 minutes, their intensity remaining practically constant. Afterwards the pulse normalized whilst accelerated respiration continued. The latter became normal step by step within 30-40 minutes. The effect of cocaine upon the motor function of the gastro-intestinal tract is generally analogous to the action of prontosil.

Our examinations permit conclusions being drawn as to the influence of prontosil and cocaine in radiological practice regarding differential diagnosis in gastro-intestinal diseases.

**835 Roentgen-diagnostic Significance of Some Pharmacological Effects for Accurate Diagnosis of Gastric Disorders**

STERN B. M. SHTEFKA /*Leipzig (DDR)*

1. Functioning of the gastric nerves accompanying inflammatory changes and tumors may frequently form a certain obstacle to accurate diagnosis of the main disorder.

2. This induced the author to search for pharmacological effects capable of acting on the functional condition of the gastric nerves and of contributing in the elimination of obstacles.

3. Parallel results were obtained in preparing the patient by means of a mixture consisting of a weak prepared solution with a small quantity of adrenalin. These two preparations contribute in a defined ratio to the reduction and elimination of swellings of the gastric mucosa. The mixture is taken by the patient according to a fixed schedule in the course of a meal prior to X-ray examination.

4. Numerous publications established that in the presence of an inflammation or tumor of the gastric mucosa one must always bearing in mind the nervous regulation of the smooth muscular matter, rapid reduction of inflammatory changes in the patient, as well as to provide connection with others, sympathizing, improving thereby the visibility of the subject area.

5. In the presence of what gastric peristoles even nonfunctional tests experiments do not always supply the material necessary for a plausible diagnostic decision, so the indirect swelling of the gastric muscles. In such cases the pharmacological effect of morphine is recommended. This pharmacological test supplies the prerequisites for a considerable increase in the value of peristolic waves as a method for the detection of an otherwise masking in the so-called small forms of gastritis.

6. Continuous spasms accompanying many a gastric disorder can be eliminated in some cases with the aid of the pharmacological influence of physostigmine (tetradrine) — as in the absence of cancer induction. This has a mild and sufficiently rapid spasmodic effect, enhancing the value of the X-ray examination.

7. The factors enumerated above as pharmacological influence can facilitate the solution of a number of diagnostic problems and the accuracy of the main diagnosis, as well as to reduce the number of gastric disorders not responsible for adenopathy.

**836 Osteoporosis as a Sign of Disease Dystrophy**

SPIGENDINE, G. A. *Zhdanov (USSR)*

Moskau (Sowjetunion)

Osteoporosis develops by reflexive action and represents the result of deep seated neurotic disorders of the bone type. Experimental investigation by G. A. Linderström and D. G. Korsakoff has demonstrated that even a transient hyperexcitation of the afferent impulses by a momentary block of the sympathetic nervous system rapidly arrested and we observed that the osteoporosis disappeared in the total number of the bone tissue. This was also determined by dysrhythmic changes in the elements of the bone tissue. The lumbar and vertebral are thinned, flattened and sometimes deformed. The nuclei of the endosteal cells surrounding the lumbar and vertebral are subjected to degenerative changes and the vertebral bone marrow is transformed to fibrous connective tissue. The degeneration of the lumbar and the vertebral changes occur mainly in the aged and the elderly, and the bone tissue appears later in the form of degenerations which do not bear the chief weight and loss important from the functional standpoint. The bone tissue, arranged according to laws of force and carrying a larger part of the functional burdens, do not change but are in some cases reinforced.

i.e., they thicken.

The radiographic method appears to be the only logical and objective means of recognizing osteoporosis in the living subject. The radiological detection of osteoporosis by signs of the soft tissues, by responses with direct enlargement, and tomography, the assessment of its cause, the degree and character, and its evolution, all bear no importance diagnostic and prognostic significance.

of Technical Sciences, M.M. Melik-Zade, Candidate of Chemical  
Sciences.

PURPOSE: This collection of articles is intended for chemical  
engineers, technicians, and refiners concerned with advanced  
methods of petroleum conversion.

CONTENTS: The collection presents an analysis of different  
types of crude extracted in Azerbaijan and of the products  
recovered from these crude through petroleum conversion  
processes. The dewatering, desalting and demineralization of crude  
is described and the suitability of these crudes for the  
refining of diesel fuel is discussed. Results of the catalytic  
cracking performed over a fluidized bed aromatic catalyst  
and the chemical composition of gasoline produced by two  
types of catalytic cracking are analyzed. Applications of two  
types of catalysts as well as catalytic circulation in a hyper-  
thermocoker are reviewed. Various low oil additives and  
are outlined. References accompany individual articles.

Arustamov, A.S.

TITLE: The Preparation of Baku Petroleum for Processing

PERIODICAL: Sb. tr. Azerb. n.-i. in-t rafinererabat, prom-sti, 1958, Nr 2,  
pp 16 - 33 (Azerb. summary)

ABSTRACT: A comprehensive thermomechanical process has been developed for preparing Baku petroleum for processing. Demulsification is carried out at a temperature of 110 - 140°C and a pressure of up to 6 atm, and the decomposition of emulsion is carried out in a mixer, where the preliminarily heated petroleum is subjected to intensive mixing. The separation of the principal mass of drill water is carried out in the first group of dehydrators. The second mixer is fed with petroleum, containing 2 - 3% of water, and washing water; as a result of vigorous mixing the salts pass into the washing water. The settling of the

washing water is carried out in the second sections of the dehydrators, after which the petroleum is cooled and passes into the storage tank for the prepared petrolsum. The method developed makes it possible to reduce the consumption of demulsifier by 55 - 60%.

TITLE: Hydrocarbons of the naphthalene series in naphtha and gas oils from catalytic cracking

PUBLICATION: Khimiya i tekhnologiya topliv i masel, no.1, 1963,  
16-19

TEXT: Alkyl naphthalenes were isolated from naphtha and light and heavy gas oils from catalytic cracking to satisfy the increasing industrial demand for phthalic anhydride. The naphthalene hydrocarbons were isolated from aromatic portions of the oils separated on silica gel and distilled to produce 10°C cuts. Alkylnaphthalenes in the cuts were separated via picrate formation. The naphtha fractions contained naphthalene (0.59% of the original naphtha),  $\beta$ -methylnaphthalene (3.66%), 1,6-dimethylnaphthalene (0.15%). The light gas oil fractions contained dimethylnaphthalenes (2.05%) and trimethylnaphthalenes (2.43%). The heavy gas oil fractions contained dimethylnaphthalenes (3.3%), trimethylnaphthalenes (1.38%) and tetramethylnaphthalenes (1.12%).  
There are 5 tables.
